

Staging as a Mechanism for Algorithm Derivation

Nicolas Feltman

September 30, 2013

1 Introduction

This document presents some preliminary work on a staged language, STAG, useful for deriving complicated algorithms. Section 2 covers the work on the language so far. We then compare this to some relevant literature in Section 3. In Section ??, we give a proposal for how to move forward with the language.

2 Current Work

2.1 Terms, Types, and Stages

A grammar for STAG is shown in Figure 1. It is currently a zeroth-order language, having no mechanisms to introduce functions. As a stopgap, we have included a notion of “external functions” which can be eliminated through application, but have no introduction forms. These functional deficiencies aside, the language supports both products and sums.

Types in the language are split into two parts: the *pretype* and the *stage*. The pretype is just the standard algebraic data type that we all know and love; it indicates *what* a term will reduce to. The stage, currently at the coarse granularity of $\mathbb{1}$ and $\mathbb{2}$, is an indication of *when* a term will be fully computed.

The rules relating types and terms are given in Figure 2. The structure of the core typing judgement is entirely standard. The nullary terms (currently just the unit value) are all explicitly annotated with a stage. The non-nullary terms essentially preserve the stage of their inputs, except for **save**, which transitions an expression from $\mathbb{1}$ to $\mathbb{2}$. From this, it is apparent that a stage $\mathbb{1}$ term cannot depend on any stage $\mathbb{2}$ terms. This property can be justified by the notion that the program gets “more reduced” as time goes on, and that a term can be no more reduced than those it depends on.

STAG has one additional peculiar feature. The predicate of a case statement can be stage $\mathbb{2}$ while the branches have subterms with stage $\mathbb{1}$. This implies that some computation in a branch must be performed even before we know which branch to take. This feature, called *speculation*, will be explored more later.

Figure 1: STAG Grammar

$$\begin{aligned}
\langle stage \rangle &= \mathbb{1} \mid \mathbb{2} \\
\langle type \rangle &= \text{unit} \\
&\mid \langle type \rangle \times \langle type \rangle \\
&\mid \langle type \rangle \rightarrow \langle type \rangle \\
&\mid \bigcirc \langle type \rangle \\
\langle exp \rangle &= () \\
&\mid (\langle exp \rangle, \langle exp \rangle) \\
&\mid \pi_1 \langle exp \rangle \mid \pi_2 \langle exp \rangle \\
&\mid \lambda \langle var \rangle . \langle exp \rangle \\
&\mid \langle var \rangle \\
&\mid \langle exp \rangle \langle exp \rangle \\
&\mid \text{save } \langle exp \rangle \\
&\mid \text{next } \langle exp \rangle \\
&\mid \text{prev } \langle exp \rangle \\
\langle cont \rangle &= \cdot \\
&\mid \langle cont \rangle, \langle var \rangle : \langle type \rangle^{\langle stage \rangle}
\end{aligned}$$

2.2 Evaluation

The evaluation is given in Figure 3. Were it complete, it would contain a definition of values (which we predict to be unchanged by the staging system), and a big-step semantics relating terms to values. The big-step evaluation should be indexed by the stage at which it completes. That is, we have both $\Downarrow_{\mathbb{1}}$ and $\Downarrow_{\mathbb{2}}$. Also, the bigstep semantics will reflect that speculation occurs down both branches of a case as part of $\Downarrow_{\mathbb{1}}$ reduction.

2.3 Stage Splitting

The core operation of interest is the process of “stage splitting,” wherein a term with stage 2 is converted to a precomputed part, and a residual that depends on that precomputed part. Specifically, we introduce a judgement “ $\Gamma \vdash e \overset{2}{\rightsquigarrow} [p, x.r]$ ”, which can be read “under the context Γ , e stage-splits into a precomputation p , and a residual r which is open on x ”. The idea is that p contains the parts of e that are stage 1, r contains the parts of e that are stage 2, and the reduced value of p is bound to x when evaluating r .

Note that the precomputation and residual are not actually terms in STAG. They are terms in a simpler language, called DOE, which is essentially STAG without the staging constructs. The grammar for DOE is shown in Figure 4. The typing rules for DOE are not shown, but can be guessed.

Figure 2: Typing Rules

$$\frac{\cdot}{\Gamma \vdash^\sigma () : \text{unit}} \quad (1)$$

$$\frac{\Gamma \vdash^\sigma e_1 : A \quad \Gamma \vdash^\sigma e_2 : B}{\Gamma \vdash^\sigma (e_1, e_2) : A \times B} \quad (2)$$

$$\frac{\Gamma \vdash^\sigma e : A \times B}{\Gamma \vdash^\sigma \pi_1 e : A} \quad (3)$$

$$\frac{\Gamma \vdash^\sigma e : A \times B}{\Gamma \vdash^\sigma \pi_2 e : B} \quad (4)$$

$$\frac{\Gamma, x : A^\sigma \vdash e : B}{\Gamma \vdash^\sigma (\lambda x : A. e) : A \rightarrow B} \quad (5)$$

$$\frac{x : A^\sigma \in \Gamma}{\Gamma \vdash^\sigma x : A} \quad (6)$$

$$\frac{\Gamma \vdash^\sigma e_1 : A \rightarrow B \quad \Gamma \vdash^\sigma e_2 : A}{\Gamma \vdash^\sigma e_1 e_2 : B} \quad (7)$$

$$\frac{\Gamma \vdash^1 e : A}{\Gamma \vdash^2 \text{save } e : A} \quad (8)$$

$$\frac{\Gamma \vdash^2 e : A}{\Gamma \vdash^1 \text{next } e : \bigcirc A} \quad (9)$$

$$\frac{\Gamma \vdash^1 e : \bigcirc A}{\Gamma \vdash^2 \text{prev } e : A} \quad (10)$$

Figure 3: Typing Rules

$$\frac{\cdot}{()_{\sigma} \Downarrow_{\sigma} ()} \quad (11)$$

$$\frac{e \Downarrow_{\sigma} v \quad f v \Downarrow v'}{f e \Downarrow_{\sigma} v'} \quad (12)$$

$$\frac{e \Downarrow_{\sigma} (v_1, v_2)}{\pi_1 e \Downarrow_{\sigma} v_1} \quad (13)$$

$$\frac{e \Downarrow_{\sigma} (v_1, v_2)}{\pi_2 e \Downarrow_{\sigma} v_2} \quad (14)$$

$$\frac{e \Downarrow_{\sigma} v}{\iota_1 e \Downarrow_{\sigma} \iota_1 v} \quad (15)$$

$$\frac{e \Downarrow_{\sigma} v}{\iota_2 e \Downarrow_{\sigma} \iota_2 v} \quad (16)$$

$$\frac{e_1 \Downarrow_{\sigma} v_1 \quad e_2 \Downarrow_{\sigma} v_2}{(e_1, e_2) \Downarrow_{\sigma} (v_1, v_2)} \quad (17)$$

$$\frac{e_1 \Downarrow_{\sigma} v_1 \quad [v'/x]e_2 \Downarrow_{\sigma} v_2}{\text{let } x = e_1 \text{ in } e_2 \Downarrow_{\sigma} v_2} \quad (18)$$

$$\frac{e_1 \Downarrow_1 v_1 \quad [v'/x]e_2 \Downarrow_p v_2}{\text{let } x = e_1 \text{ in } e_2 \Downarrow_p v_2} \quad (19)$$

$$\frac{e_1 \Downarrow_p v_1 \quad e_2 \Downarrow_p v_2}{\text{let } x = e_1 \text{ in } e_2 \Downarrow_p \text{let } x = v_1 \text{ in } v_2} \quad (20)$$

$$\frac{e \Downarrow_{\sigma} (\iota_i v) \quad [v/x_i]e_i \Downarrow_{\sigma} v}{\text{case } e \text{ of } x_1.e_1 \mid x_2.e_2 \Downarrow_{\sigma} v} \quad (21)$$

$$\frac{e \Downarrow_1 (\iota_i v) \quad [v/x_i]e_i \Downarrow_p v}{\text{case } e \text{ of } x_1.e_1 \mid x_2.e_2 \Downarrow_p v} \quad (22)$$

$$\frac{e \Downarrow_p v \quad e_1 \Downarrow_p v_1 \quad e_2 \Downarrow_p v_2}{\text{case } e \text{ of } x_1.e_1 \mid x_2.e_2 \Downarrow_p \text{case } v \text{ of } x_1.v_1 \mid x_2.v_2} \quad (23)$$

$$\frac{e : A @ 1}{\text{save } e \Downarrow_2} \quad (24)$$

Figure 4: DOE Grammar

$$\begin{aligned}
\langle type \rangle &= \text{unit} \mid \langle type \rangle \times \langle type \rangle \mid \langle type \rangle + \langle type \rangle \\
\langle exp \rangle &= \langle func \rangle \langle exp \rangle \\
&\mid () \\
&\mid (\langle exp \rangle, \langle exp \rangle) \\
&\mid \pi_1 \langle exp \rangle \mid \pi_2 \langle exp \rangle \\
&\mid \iota_1 \langle exp \rangle \mid \iota_2 \langle exp \rangle \\
&\mid \text{let } \langle var \rangle = \langle exp \rangle \text{ in } \langle exp \rangle \\
&\mid \langle var \rangle \\
&\mid \text{case } \langle exp \rangle \text{ of } \langle var \rangle . \langle exp \rangle \mid \langle var \rangle . \langle exp \rangle \\
\langle cont \rangle &= \cdot \\
&\mid \langle cont \rangle, \langle var \rangle : \langle type \rangle
\end{aligned}$$

The full rules for splitting are shown in Figure 5. In two of the rules, I reference another judgement, of the form “ $\Gamma \vdash e \xrightarrow{1} e'$ ”. This means that the one-stage STAG term e simply translates to a DOE term e' . There are no surprises in how this works, so the details are omitted.

Even without a semantics done, we can think of two theorems that should hold true of stage splitting. Namely, that good types in lead to good types out. Explicitly:

$$\begin{array}{ll}
\text{If } \Gamma \vdash e : \tau @ 1 & \text{If } \Gamma \vdash e : \tau @ 2 \\
\text{then } \Gamma \vdash e \xrightarrow{1} e' & \text{then } \Gamma \vdash e \xrightarrow{2} [p, x.r] \\
\text{and } \Gamma \vdash e' : \tau & \text{and } \Gamma_1 \vdash p : \tau' \\
& \text{and } \Gamma_2, x : \tau' \vdash r : \tau
\end{array}$$

Note that I’m implicitly abusing the identical structures of pretypes in STAG and types in DOE. Also, for any stage σ , we define Γ_σ as,

$$(\cdot)_\sigma = \cdot \tag{25}$$

$$(\Gamma, x : \tau @ \sigma)_\sigma = \Gamma_\sigma, \tau \tag{26}$$

$$(\Gamma, x : \tau @ \sigma')_\sigma = \Gamma_\sigma \quad \text{where } \sigma \neq \sigma' \tag{27}$$

2.4 Implementation

I have an implementation of stage-splitting in SML. Currently, the code only keeps track of stage, and not the pre-type.

[Add results.]

Figure 5: Term Splitting

$$\frac{x : A^1 \in \Gamma}{\Gamma \vdash^1 x : A \rightsquigarrow [(x, ()), \dots x]} \quad (28)$$

$$\frac{\Gamma, x : A^1 \vdash e : B \rightsquigarrow [c, l.r]}{\Gamma \vdash^1 (\lambda x : A. e) : A \rightarrow B \rightsquigarrow [(\lambda x : |A|_1. c, ()), \dots (\lambda(x, l) : |A|_2 \times \tau.r)]} \quad (29)$$

$$\frac{\Gamma \vdash^1 e_1 : A \rightarrow B \rightsquigarrow [c_1, l_1.r_1] \quad \Gamma \vdash^1 e_2 : A \rightsquigarrow [c_2, l_2.r_2]}{\Gamma \vdash^1 e_1 \ e_2 : B \rightsquigarrow \left[\text{let } y = (\pi_1 c_1)(\pi_1 c_2) \text{ in } (\pi_1 y, (\pi_2 c_1, \pi_2 c_2, \pi_2 y)), \right.} \quad (30)$$

$$\left. l. (\text{let } x_1 = \pi_1 l \text{ in } r_1)(\text{let } x_2 = \pi_2 l \text{ in } r_2, \pi_3 l) \right]$$

$$\frac{\cdot}{\Gamma \vdash^1 () : \text{unit} \rightsquigarrow [(), \dots ()]} \quad (31)$$

$$\frac{\Gamma \vdash^1 e_1 : A \rightsquigarrow [p_1, l_1.r_1] \quad \Gamma \vdash^1 e_2 : B \rightsquigarrow [p_2, l_2.r_2]}{\Gamma \vdash^1 (e_1, e_2) : A \times B \rightsquigarrow [(p_1, p_2), l. (\text{let } l_1 = \pi_1 l \text{ in } r_1, \text{let } l_2 = \pi_2 l \text{ in } r_2)]} \quad (32)$$

$$\frac{\Gamma \vdash^1 e : A \times B \rightsquigarrow [p, l.r]}{\Gamma \vdash^1 \pi_1 e : A \rightsquigarrow [\pi_1 p, l. \pi_1 r]} \quad (33)$$

$$\frac{\Gamma \vdash^1 e : A \times B \rightsquigarrow [p, l.r]}{\Gamma \vdash^1 \pi_2 e : B \rightsquigarrow [\pi_2 p, l. \pi_2 r]} \quad (34)$$

$$\frac{\Gamma \vdash^2 e : A \rightsquigarrow^2 [p, l.r]}{\Gamma \vdash^1 \text{next } e : \bigcirc A \rightsquigarrow [((), p), l.r]} \quad (35)$$

3 Related Work

3.1 Partial Evaluation

One can immediately see a connection between this work and partial evaluation. Both involve the idea of specializing a piece of code to some of its inputs, leaving a residual that depends only on the remaining inputs. But stage splitting is actually only part of partial evaluation. At its core, stage splitting is “factor out the first stage, reduce it to a value, and express the second stage abstractly over that value,” whereas partial evaluation is “factor out the first stage, reduce it to a value, and specialize the code of the second stage to that value.” Expressed equationally,

$$\begin{array}{ll} \textbf{Partial Evaluation:} & p(f, a) = f_a \quad \text{s.t. } f_a(b) = f(a, b) \\ \textbf{Stage Splitting:} & s(f) = (f_1, f_2) \quad \text{s.t. } f_2(f_1(a), b) = f(a, b) \end{array}$$

Immediately, we note that stage splitting has broader application than partial evaluation, since the latter requires that p (specifically, some code-specializing apparatus) and a be available at the same time. If this requirement is satisfied, then we can compare apples to apples by creating a partial evaluator out of a stage splitter:

$$f_a = (\text{let } x = f_1(a) \text{ in } \lambda b. f_2(x, b))$$

From this view, we see that partial evaluators are more powerful because they can avoid memory loads, prune unused branches, and even duplicate recursive code for further specialization. These are largely free wins, except for the recursive code generation, which might have large space costs.

3.2 Temporal Logic

There are two papers (called “circle” and “square”) by Rowan Davies which give a justification for binding time analysis in modal logics. Those papers feel stylistically similar to this work. Circle, in addition to its other contributions, gives a particularly good account of the difference between its style (which we use), and the rest of the literature.

There’s an important question that our work will need to answer about the difference between the logic that our type system induces and those of Davies. In particular, what does it mean that our language has no `prev` operator?

3.3 Speculation

I can find nothing in the literature that looks like our speculation. That’s probably because speculation is unsafe (especially around side effects), and so it would be a terrible idea in a system without lots of programmer direction.
